# Dynamic Memory Allocation: Advanced Concepts

Assignment Project Exam Help

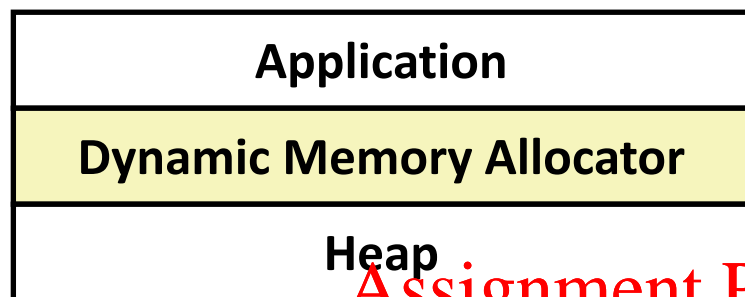

15-213/18-213/14-5

Introduction to Com <https://eduassistpro.github.io/>

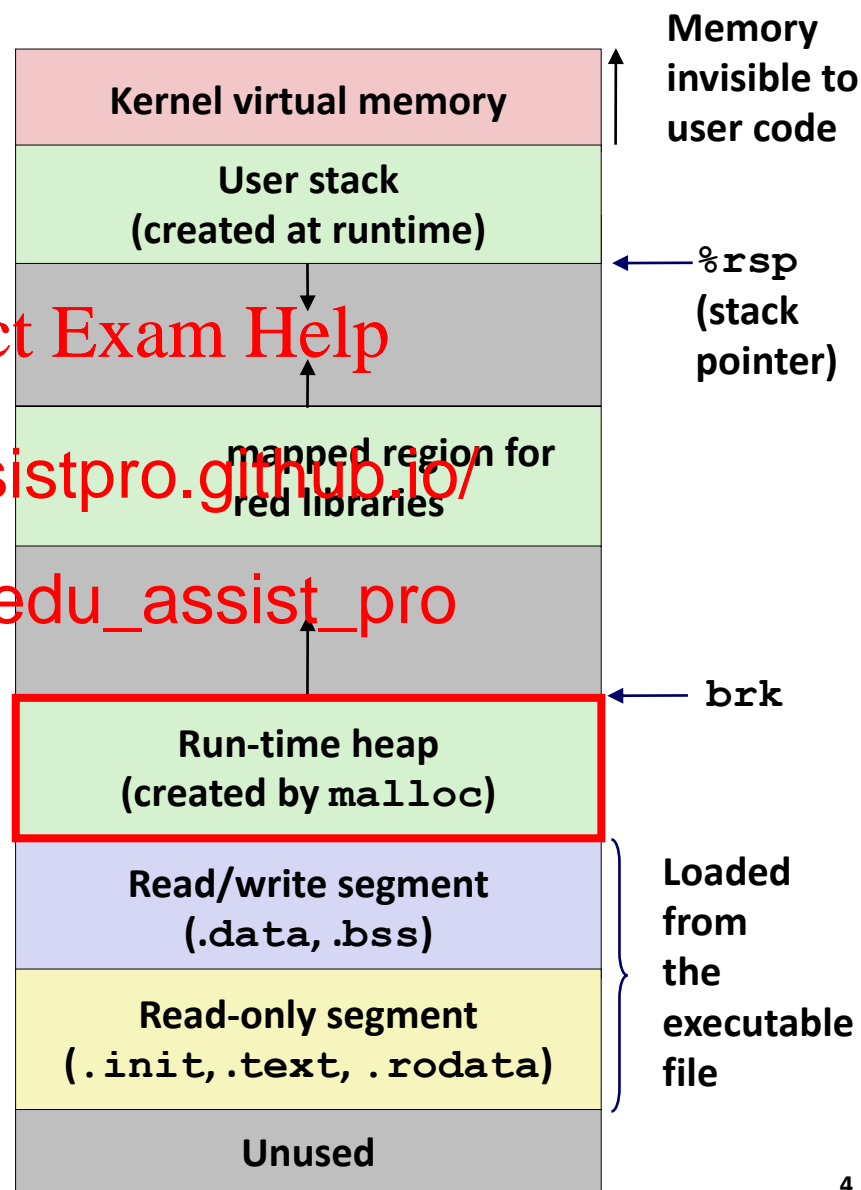

16<sup>th</sup> Lecture, October 22, 2020

Add WeChat edu\_assist\_pro

# Review: Dynamic Memory Allocation

- Programmers use *memory allocators* (`malloc`) to acquire virtual memory (VM) at run time.
  - for data structures whose size is only known at runtime
- Dynamic memory allocators manage an area of process VM known as the *heap*.

# Review: Keeping Track of Free Blocks

## ■ Method 1: *Implicit list* using length—links all blocks

Need to tag each block as allocated/free

Assignment Project Exam Help

## ■ Method 2: *Explicit* links using pointers

Need space for pointers

## ■ Method 3: *Segregated free list*

- Different free lists for different size classes

## ■ Method 4: *Blocks sorted by size*

- Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

# Review: Implicit Lists Summary

- **Implementation: very simple**
- **Allocate cost:**
  - linear time worst case
- **Free cost:**
  - constant time
  - even with coalesce
- **Memory Overhead:**
  - Depends on placement policy
  - Strategies include first fit, next fit, and best fit
- **Not used in practice for `malloc/free` because of linear-time allocation**
  - used in many special purpose applications
- **However, the concepts of splitting and boundary tag coalescing are general to *all* allocators**

# Keeping Track of Free Blocks

- Method 1: *Implicit list* using length—links all blocks

Assignment Project Exam Help

- Method 2: *Explicit* links using pointers

- Method 3: *Segregated free list*

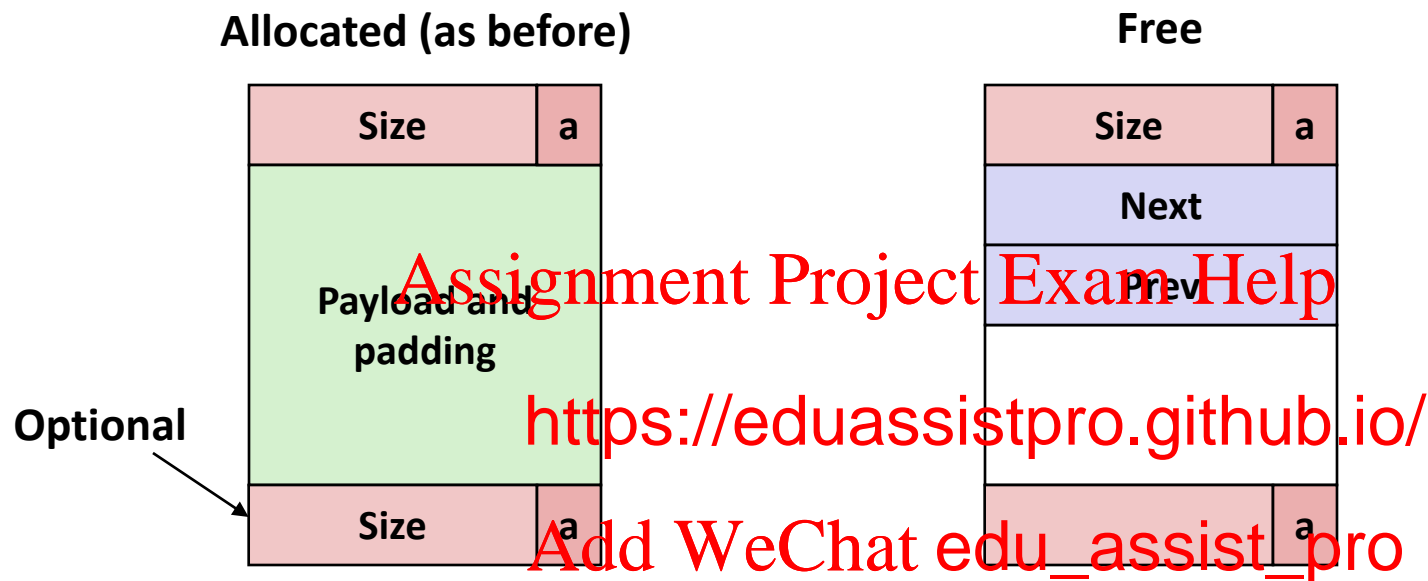

- Different free lists for different size classes

- Method 4: *Blocks sorted by size*

- Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

# Explicit Free Lists

## ■ Maintain list(s) of *free* blocks, not *all* blocks

- Luckily we track only free blocks, so we can use payload area
- The “next” free block could be anywhere
  - So we need to store forward/back pointers, not just sizes
- Still need boundary tags for coalescing
  - To find adjacent blocks according to memory order

# Explicit Free Lists

## ■ Logically:

Assignment Project Exam Help

## ■ Physically: block <https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

## Before

<https://eduassistpro.github.io/>

## After

# Freeing With Explicit Free Lists

- **Insertion policy:** Where in the free list do you put a newly freed block?
- **Unordered**
  - LIFO (last-in-first-out) policy
    - Insert freed block at the beginning of free list
  - FIFO (first-in-first-out) policy
    - Insert freed block at the end of free list
  - **Pro:** simple and constant time
  - **Con:** studies suggest fragmentation is worse than address ordered
- **Address-ordered policy**
  - Insert freed blocks so that free list blocks are always in address order:  
 $addr(prev) < addr(curr) < addr(next)$
  - **Con:** requires search
  - **Pro:** studies suggest fragmentation is lower than LIFO/FIFO

# Freeing With a LIFO Policy (Case 1)

conceptual graphic

*Before*

Add WeChat edu\_assist\_pro

- Insert the freed block at the root

*After*

# Freeing With a LIFO Policy (Case 2)

conceptual graphic

*Before*

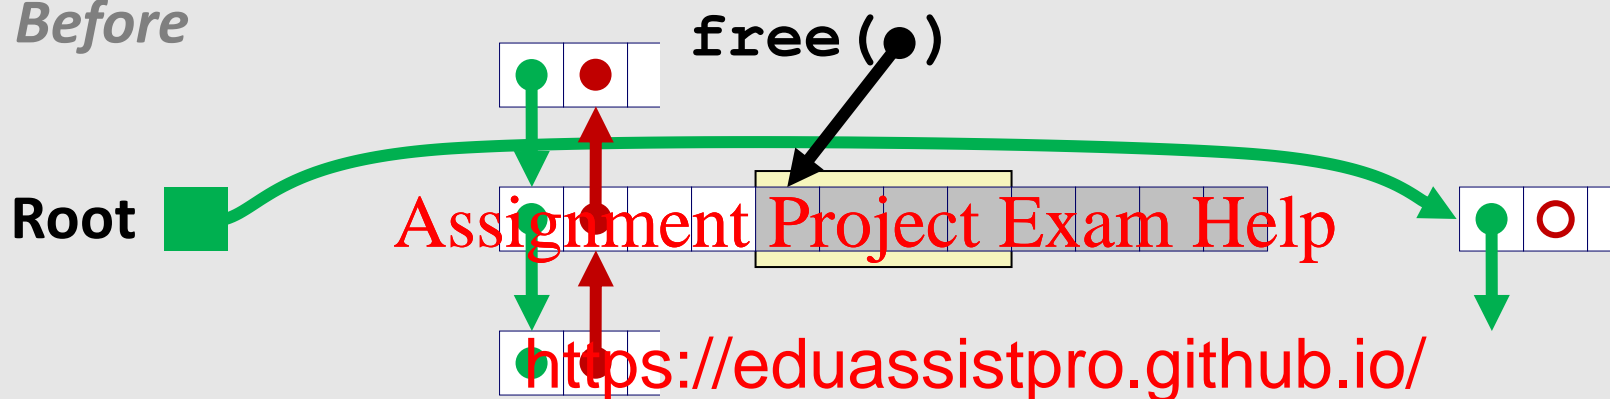

Add WeChat edu\_assist\_pro

- Splice out adjacent successor blocks, and insert the new block at the root of the list

*After*

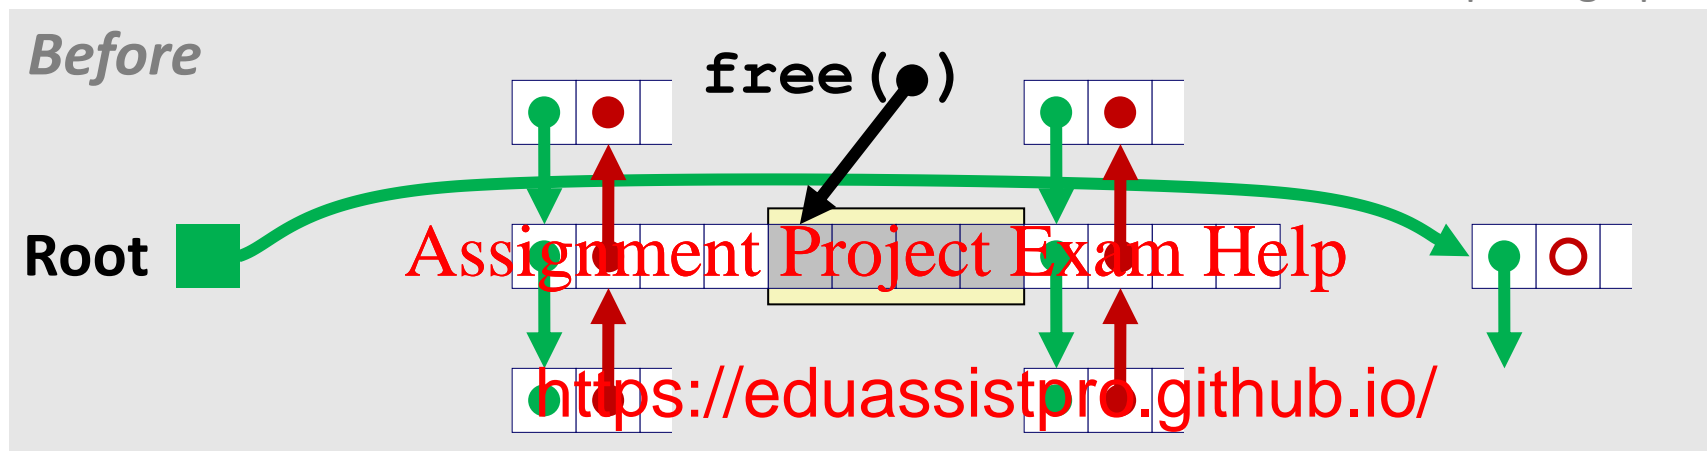

- **Splice out adjacent predecessor blocks, and insert the new block at the root of the list**

# Freeing With a LIFO Policy (Case 4)

conceptual graphic

- Splice out adjacent predecessor or blocks, coalesce all 3 blocks, and insert the new block at the root of the list

# Some Advice: An Implementation Trick

<https://eduassistpro.github.io/>

- Use circular, doubly-linked list
- Support multiple approaches with different data structure
- First-fit vs. next-fit
  - Either keep free pointer fixed or move as search list
- LIFO vs. FIFO
  - Insert as next block (LIFO), or previous block (FIFO)

# Explicit List Summary

## ■ Comparison to implicit list:

- Allocate is linear time in number of *free* blocks instead of *all* blocks
  - *Much faster* when most of the memory is full
- Slightly more complicated allocate and free because need to splice blocks in and out of the list
- Some extra space needed for each block)
  - Does this increase internal frag

# Segregated List (Seglist) Allocators

- Each *size class* of blocks has its own free list

- Often have separate classes for *size*
- For larger sizes: One class for each size  $[2^i + 1, 2^{i+1}]$

# Seglist Allocator

- Given an array of free lists, each one for some size class
- To allocate a block of size  $n$ :
  - Search appropriate free list for block of size  $m \geq n$  (i.e., first fit)
  - If an appropriate block is found:
    - Split block  $a$  into two blocks: one of size  $n$  and the remainder of size  $a - n$ . Add the remainder to the free list.
    - If no block is found, go to the next free list.
  - Repeat until block is found.
- If no block is found:
  - Request additional heap memory from OS (using `sbrk()`)
  - Allocate block of  $n$  bytes from this new memory
  - Place remainder as a single free block in appropriate size class.

Add WeChat edu\_assist\_pro

# Seglist Allocator (cont.)

## ■ To free a block:

- Coalesce and place on appropriate list

## ■ Advantages of seglist allocators vs. non-seglist allocators (both with first-f

- Higher throughput
  - log time for power-of-two size ar time
- Better memory utilization
  - First-fit search of segregated free list approximates a best-fit search of entire heap.
  - Extreme case: Giving each block its own size class is equivalent to best-fit.

Add WeChat edu\_assist\_pro

# Reading Uninitialized Memory

- Assuming that heap data is initialized to zero

```
/* return y = Ax */
int *matvec(int **A, int *x) {
    int *y = malloc(N * sizeof(int));
    int i, j;

    for (i=0; i<N; i++)
        for (j=0; j<N; j++)
            y[i] += A[i][j]*x[j];
    return y;
}
```

- Can avoid by using `calloc`

# Overwriting Memory

- Allocating the (possibly) wrong sized object

```
int **p;
```

```
p = malloc(N*
```

```
for (i=0; i<N
```

```
    p[i] = malloc(M*sizeof(  
    )
```

# Implicit Memory Management: Garbage Collection

- ***Garbage collection***: automatic reclamation of heap-allocated storage—application never has to explicitly free memory

```
void foo() {  
    int *p = malloc  
    return; /* p  
}
```

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

- **Common in many dynamic languages:**
  - Python, Ruby, Java, Perl, ML, Lisp, Mathematica
- **Variants (“conservative” garbage collectors) exist for C and C++**
  - However, cannot necessarily collect all garbage

# Garbage Collection

- **How does the memory manager know when memory can be freed?**
  - In general we cannot know what is going to be used in the future since it depends on conditionals
  - But we can tell that certain blocks cannot be used if there are no pointers to them
- **Must make certain assumptions**
  - Memory manager can distinguish pointers from non-pointers
  - All pointers point to the start of a block
  - Cannot hide pointers (e.g., by coercing them to an `int`, and then back again)

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Classical GC Algorithms

- **Mark-and-sweep collection (McCarthy, 1960)**
  - Does not move blocks (unless you also “compact”)
- **Reference counting (Collins, 1960)**
  - Does not move blocks (not discussed)
- **Copying collection**
  - Moves blocks (not discussed)
- **Generational Collectors (Lieberman and Gottlieb, 1983)**
  - Collection based on lifetimes
    - Most allocations become garbage very soon
    - So focus reclamation work on zones of memory recently allocated
- **For more information:**

**Jones and Lin, “*Garbage Collection: Algorithms for Automatic Dynamic Memory*”, John Wiley & Sons, 1996.**

Assignment Project Exam Help

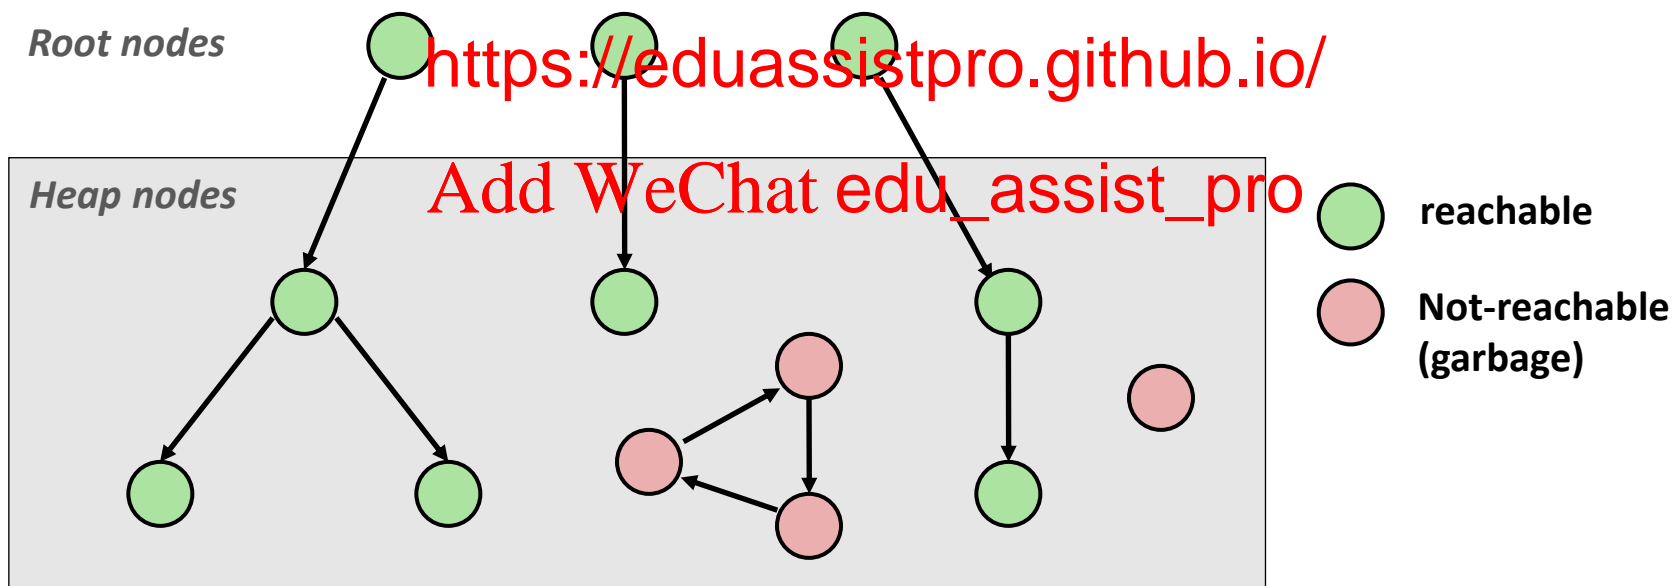

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Memory as a Graph

## ■ We view memory as a directed graph

- Each block is a node in the graph
- Each pointer is an edge in the graph
- Locations not in the heap that contain pointers into the heap are called **root** nodes (e.g., registers, locations on the stack, global variables)

A node (block) is **reachable** if there is a path from any root to that node.

Non-reachable nodes are **garbage** (cannot be needed by the application)

# Mark and Sweep Collecting

## ■ Can build on top of malloc/free package

- Allocate using `malloc` until you “run out of space”

## ■ When out of space:

- Use extra **mark bit** in the head of each block
- **Mark:** Start at `root` and traverse each block
- **Sweep:** Scan all blocks and free those not marked

# Assumptions For a Simple Implementation

## ■ Application

- **new (n)**: returns pointer to new block with all locations cleared
- **read (b, i)**: read location **i** of block **b** into register
- **write (b, i, v)**: write **v** into location **i** of block **b**

Assignment Project Exam Help

## ■ Each block will have <https://eduassistpro.github.io/>

- addressed as **b[-1]**, for a block **b**
- Used for different purposes in different applications

Add WeChat edu\_assist\_pro

## ■ Instructions used by the Garbage Collector

- **is\_ptr (p)**: determines whether **p** is a pointer
- **length (b)**: returns the length of block **b**, not including the header
- **get\_roots ()**: returns all the roots

# Mark and Sweep Pseudocode

Mark using depth-first traversal of the memory graph
